

Deployment Guide

The project supports local and cloud deployment approaches. For local deployment, the FastAPI backend and Streamlit frontend are executed independently. The backend serves prediction requests while the frontend provides the user interface.

For production deployment, Docker containers can be used to package application dependencies and runtime configurations. Cloud deployment options include AWS EC2, Azure App Service, and Google Cloud Run.

Monitoring tools such as Prometheus and Grafana can be integrated for performance tracking. Logging solutions can be added to improve observability and troubleshooting capabilities.

A deployment checklist should include model verification, API testing, dependency validation, and security review.
